

# Ch 8 Solutions

## 8.1 A Solution is a Type of Mixture

# The parts of a solution are mixed evenly

- A solution is homogeneous
  - Solute—part that is dissolved
  - Solvent—part that does the dissolving

Water is considered to be a universal solvent.

Solutions can be:

Solids

Liquids

Gases

If the solute & solvent are in the same physical state, the one in greater proportion is the solvent.

# Suspension (heterogeneous mixture)

A mixture with large particles that do not dissolve

- this mixture is **NOT** a solution
- usually have to shake or stir it before using

# Solvent & Solute Particles Interact In Solutions

- When a solid dissolves in a liquid, the solute breaks apart
- Solute particles are surrounded by solvent particles and are evenly distributed in the solution

- Ionic compounds break apart in solutions
- Covalent compounds stay intact when dissolved in solutions

# Properties of Solvents Change in Solutions

A solute changes the *physical properties* of a solvent (they become more extreme)

- Freezing point of a solution becomes lower
- Boiling point of a solution becomes higher

# Diffusion & Osmosis

- Diffusion—molecules spread from an area of *higher* to *lower* concentrations
- Osmosis—diffusion of water only

# Diffusion & Cells

- Permeable—allows things to pass
- Cells have selectively permeable membranes that allow *some* substances to pass through, but not all.
- Criteria for being allowed to pass depends on:

- Size
- Shape
- Electrical charge

# 3 Types of Solutions

1. Hypertonic
2. Hypotonic
3. Isotonic

# Hypertonic

- If a cell is immersed in this, it will shrink because water flows out of the cell
- The solute concentration is greater in the solution (outside of the cell)

# Hypotonic

- If a cell is immersed in this, it will swell & possibly explode because water flows into the cell
- The solute concentration is greater inside the cell (not in the solution)

# Isotonic

- Has no effect on the direction of diffusion
- Concentration is equal on both sides of the membrane

## 8.2 The Amount of a Solute that Dissolves Can Vary

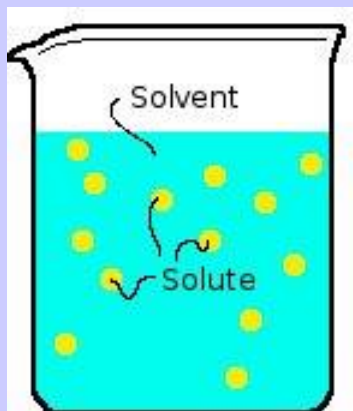

# A solution with a high concentration contains a large amount of a solute

- Concentration of a solution—the amount of solute dissolved in it at a particular temp.

– *Add solute* = increased concentration

– *Add solvent* = lowers

concentration  
(*making it more dilute*)

# Saturated Solution

- Holds the maximum amount of a solute at a certain temp.
- Supersaturated solution contains more solute than can be dissolved at a certain temp
  - Achieved by heating the solution then slowly cooling it down
  - A disturbance can cause the excess solute to come out of the solution as a precipitate (solid)

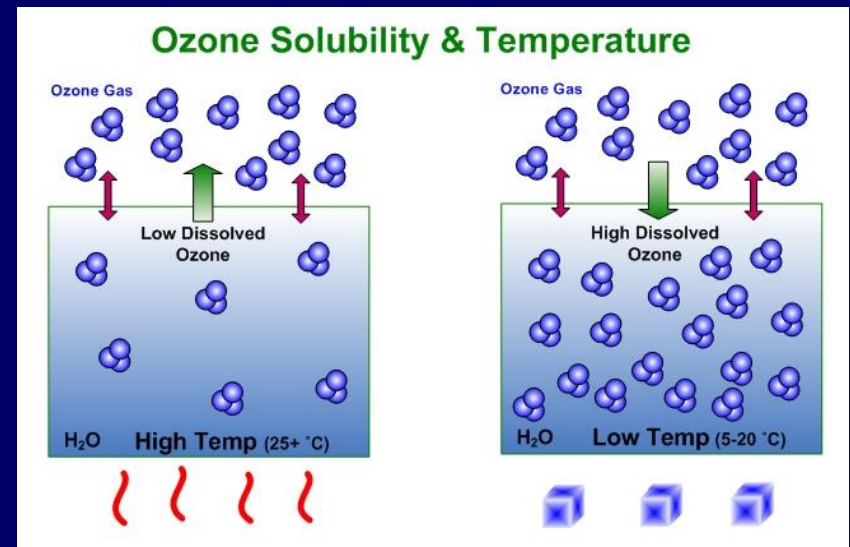

Every substance has a characteristic solubility (amount that will dissolve in a certain amount of a certain solvent at a given temp)

# Solubility of a solute can be changed

- *Increasing temp*
  - increases solubility of most solids in liquid solution
  - decreases solubility of gases in a solution
- *Increasing pressure*
  - increases solubility of gases in a solution
  - does not affect solid & liquid solutes

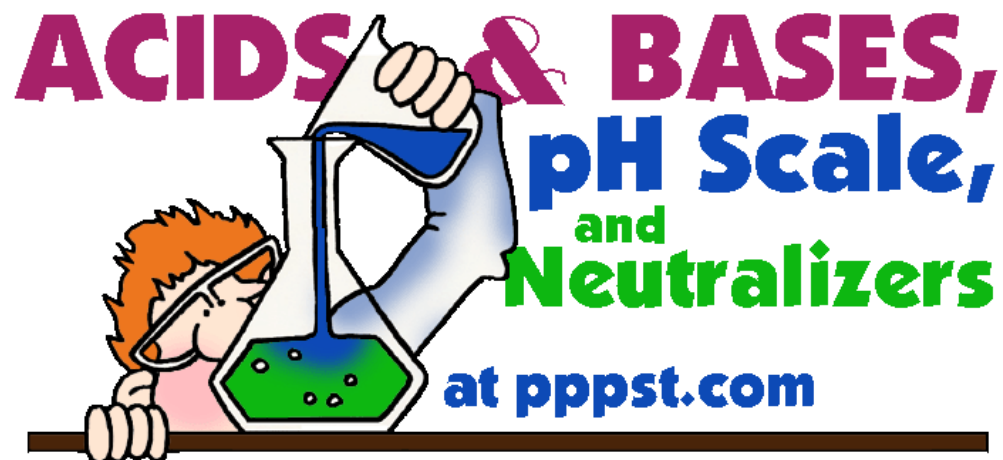

# Solubility depends on molecular structure

Depends on electrical charges of solute & solvent particles

- Polar molecules & ions dissolve in polar solvents (like water)
- Non-polar molecules (like oils)
  - do not dissolve in polar solvents
  - do dissolve in non-polar solvents

## 8.3 Solutions can be acidic, basic, or neutral

<u>Term</u>	<u>Adjective</u>
Acid	<i>acidic</i>
Base	<i>alkaline or basic</i>

# Acids & Bases have distinct properties

Acids—donate hydrogen ions (proton) to other substances when dissolved in water

- HCl (hydrochloric acid) is an example
- They taste *sour*
- React with carbonates to form carbon dioxide
- React with many metals

$H^+$

$OH^-$

Substance	pH
Battery acid	0.5
Sarac acid	1.0-1.4
Lemon juice	2.0-2.4
Vine	2.5-3.5
Orange	3.0-4.0
Strawberry	3.5
Tomato	4.0-4.5
Apple	4.0-5.0
Black coffee	5.0
Tea or healthy diet	6.5-7.5
Milk	6.5-6.8
Pure water	7.0
Healthy human saliva	6.5-7.5
Blood	7.35-7.45
Sea water	7.5-8.5
Hard soap	9.0-10.0
Household ammonia	11.5-12.5
bleach	12.5-13.5
Household lye	14.0

Courtesy of Wikipedia

# OH...It's a Base

Bases—accept hydrogen ions from other substances

$\text{OH}^- = \text{hydroxide ion}$

(*proton acceptors*)

- In water, the base NaOH (sodium hydroxide) *releases* a hydroxide ion, which can accept a hydrogen ion
- Taste *bitter*
- Feels *slippery* or *soapy*

# Copy the pH scale from the board

# Strengths of acids & bases can be *measured*

- Strong acids & bases break apart *completely* into individual ions in solution
- A weak acid or base does not break apart completely into ions in solution

Strong acids completely dissociate in water.

# Acidity of a solution is measured on the pH scale

pH scale is like a number line 0-14

- Acids = 0-6
- Bases = 8-14
- Neutral = 7

*p = power of*  
*H = hydrogen*

# Acids & Bases

## *Neutralize Each Other*

- **Acid + Base = neutralization reaction**
- **Hydrogen ion (from acid) bonds with hydroxide ion (from base) to form water**
- **Products of neutralization reactions are water & salt**

## 8.4 Metal *Alloys* are Solid Mixtures

# Humans have made alloys for thousands of years

- Alloy—solid mixture that has many of the characteristics of a solution
  - Solid (usually metal) solute is mixed with a solid metallic solvent
  - Made by melting the metal components & mixing them in the liquid state
  - Physical properties of an alloy are different from those of the solvent metal

## 2 General Types of Alloys

- Substitutional alloy—example = brass
  - Some of the Cu atoms are replaced by Zn
- Interstitial alloy—example = steel
  - C atoms occupy gaps between Fe atoms

# Alloys have many uses in modern life

- New alloys are constantly being produced in response to new technology
- Mostly includes transportation, medicine, & aerospace industries
  - Aluminum alloys are light weight, strong, & have low densities (good for cars & aircraft)
  - More dense alloys (like steel) are used in application in which weight is not an issue

*Aluminum*

*Steel*
